Pricing – part 2

S-38.041 Networking Business
Service life cycle phases

Impact on pricing

- **Introduction**: early adopters, skimming vs. aggressive growth
- **Growth**: increasing demand, little competition, high margins
- **Maturity**: differentiation pressure, tough competition, low margins
- **Decline**: cost cutting, harvesting niche segments, high margins

Graph showing:
- **Penetration**
- **Margins**

Time scale:

- **Decline**
Backbone services
Sales of capacity between pre-defined similar end-points

- Customers are other operators or individual firms
- Portfolio of services
  - point-to-point vs. multipoint
  - basic (dark fiber) vs. value-added (managed IP router service)
  - voice vs. data vs. video
- ATM being gradually replaced by Ethernet and MPLS
- Pricing based on Service Level Agreements (SLA) and traffic parameters (peak rate, mean rate, data loss probability, max delay, mean delay, etc)
Backbone services

Impact of IP

- Growth of IP traffic involves evolution from
  - inelastic to elastic applications (e.g. video, audio and voice coding)
  - guaranteed to best-effort services
  - deterministic to statistical multiplexing (ref. effective bandwidth)
  - bottleneck control to over-dimensioning
  - layer 2 VPN to layer 3 IP VPN
- Key issue: demand vs. supply of backbone capacity?
Backbone services
Service Level Agreement (SLA)

- **Service level agreement**: a documented result of a negotiation between a customer and a provider of a service that specifies the levels of availability, performance, operation and other attributes of the service.

- **Static SLA management**: SLA contract is made between two human parties and its terms cannot be changed without human intervention.

- **Dynamic SLA management**: SLAs are negotiated and contracted automatically using some signaling procedures.

- **SLA trading**: dynamic SLA management where information on service provisioning, routing, and pricing are exchanged between providers.
Backbone services

SLA evolution scenario

1. Static SLA management in telecom networks and dedicated data networks
2. Static SLA management in IP-based best effort networks
3. Static SLA management in IP diffserv (DS) networks
4. Dynamic SLA management in IP DS networks

DS has the following SLA characteristics

- Scope of large traffic aggregates (as opposed to ATM SVC)
- Typical traffic aggregates are VoIP, WWW, specific routes
- Aggregates appear as Traffic Conditioning Agreements (TCA)
- Traffic flows through DS domains (via ingress/egress nodes)
- Standardized Per-Hop-Behaviors (PHB)
  - Expedited Forwarding (EF)
  - Assured Forwarding (AF)
Backbone services

SLA traders

Access network

Core network (transit domain)

Access network

Legend

- SLA trader
- Static SLA
- Dynamic SLA

• Dynamic SLAs between peer ISPs
• Static SLAs for end-users
Backbone services
Summary of SLA trading

- SLA trading has not been tested in real deployments
- SLA trading suits best for large networks and ISPs
- Transition from static to dynamic SLA trading is a major management challenge
- Based on simulation results, SLA trading can improve network utilization by up to 40% compared to a traditional, shortest-path routed inter-domain network
- The residual bandwidth pricing strategy is suitable for SLA trading since it ensures that prices increase with SLA or link load
Internet access services

Congestion control

• The end-to-end bottleneck may occur at different points
  – In dedicated access:
    • Increase subscriber access speed (e.g. ADSL)
    • Push resource sharing closer to subscribers (e.g. HomePNA)
  – In shared access/backbone/server: apply *congestion control*

• Congestion should be optimized
  – Too much congestion ⇒ *negative network externality*
  – Too little congestion ⇒ waste of resources

• Options for congestion control
  – Over-dimensioning (waste of resources)
  – Call admission control, e.g. RSVP blocking (latest customers suffer)
  – Automatic flow control, e.g. TCP (all customers suffer)
  – Human fairness control, e.g. HomePNA (group discipline)
  – *Congestion pricing* (maximal social surplus?)
Internet access services

Congestion pricing - theory

- Congestion price is two-part: normal + externality, \( p + p_E \)
  - Social surplus maximization
    \[
    \text{(1)} \quad \max \sum_j u_j (x_j, y) - c(k), \quad \text{where} \quad y = \sum_i x_i / k, \quad k=\text{total fixed capacity}
    \]
    \[
    \Rightarrow p_E = -(1/k) \sum_j du_j(x_j, y) / dy, \quad \text{where} \quad x_j=\text{socially optimal demand}
    \]
  - Individual maximization of surplus for consumer \( i \)
    \[
    \text{(2)} \quad \max [u_i(x_i, y) - p_E x_i] \Rightarrow x_i = \bar{x}_i, \quad \text{if number of users is large}
    \]
  - Social and individual optima are the same, Nash equilibrium!
  - Congestion price converges to optimal price via tatonnement:
    network determines \( p_E \) using step (1) and publishes it, then each
    consumer \( i \) solves step (2) to find \( x_i \), and so on
  - \( u_j \) are unknown \( \Rightarrow \) network must vary \( p_E \) until finding equilibrium
  - \( y \) is unknown to consumers \( \Rightarrow \) consumers estimate it via congestion

- Congestion pricing suits for expensive bottlenecks like radio
- Congestion pricing facilitates automatic optimal capacity
  planning via the customer feedback loop
Internet access services

Congestion pricing - practice

• Time-of-day pricing (e.g. fixed-price tickets in Internet Café)
• Pricing per application & traffic type
  – Types pre-defined using diffserv, e.g. www, VoIP, etc
  – Automatic traffic classification and resource re-allocation
• Pricing per user’s willingness-to-pay
  – Price-driven separation of service classes (e.g. Paris Metro Pricing)
  – Priority service classes based on relative quality (e.g. via diffserv)

• Note that flat-rate pricing well reflects the operator’s large share of fixed cost, but cannot efficiently tackle the unavoidable problem of temporary congestion!
## Content services

### Private vs. public goods

<table>
<thead>
<tr>
<th>Private good (e.g. candy bar)</th>
<th>Public good (e.g. radio broadcast)</th>
</tr>
</thead>
<tbody>
<tr>
<td>• You consume one, there is one less for others - <em>depletetable</em></td>
<td>• <em>Nondepletable</em> – when used by one, the same amount is available to others.</td>
</tr>
<tr>
<td>• If consumed – no one else can - <em>excludable</em></td>
<td>• <em>Nonexcludable</em> – Use by one does not exclude others from using the good.</td>
</tr>
<tr>
<td>• Marginal cost &gt; 0</td>
<td>• Marginal cost ≈ 0</td>
</tr>
<tr>
<td>• Price = marginal cost. Achieved on ideal market when supply = demand</td>
<td>• Price ≈ 0 ➔ fixed cost is not recovered ➔ taxation, non-usage based fees</td>
</tr>
</tbody>
</table>
Content services

Evolution examples

- **Best-effort IP service**: Initially public good $\rightarrow$ Flat monthly fee $\rightarrow$ Congestion $\rightarrow$ Private good externality.
- **Telephone call**: In PSTN and over radio interface = private good (”candy bar”) $\rightarrow$ price/unit.
- **Value-added IP service**, e.g. VoIP: Initially usage fee. CPU and memory getting cheaper (Moore’s law) $\rightarrow$ Marginal cost of new customer $\approx 0$ $\rightarrow$ Flat-rate.
- **Digital Content**: Marginal cost $\approx 0$ $\rightarrow$ Copyright and IPR control enable both private and public goods. Copyright violations, e.g. peer-to-peer traffic $\rightarrow$ development of digital rights management (DRM) or bundling with other private goods!
Service bundling
Vertical vs. horizontal bundling in GSM

• Vertical bundling
  – Bundling of access with content
  – For instance weather report over SMS

• Horizontal bundling
  – Bundling of access services (e.g. multiple radios, circuit vs. packet-switched, voice vs. data)
  – Bundling of vertically bundled services (e.g. weather report over SMS vs. WAP)

• Bundling enables
  – Cross-subsidies and service differentiation
  – Value-based pricing, i.e. flexible testing of subscriber’s willingness-to-pay
Service bundling
Roll-out of new services

• Cross-subsidies enable early roll-out of still non-profitable services
• Operator can also take risk of new handsets via handset subsidies
Value-based pricing model

Mobile operator view

- Maximise value per byte.
  \[ p = \max \{ \frac{v}{B} \} \]
- Planes
  - Content Providers (S)
  - Mobile Operators (OP)
  - Consumers (C)
- Interfaces
  - Value interface (V)
  - Transport-content interface (TC)
- Competition at V and TC
- Experimentation via TC
- Revenue sharing at TC

Source: Renjish Kumar Kaleelatzicathu Ratna, 2004
Case: DoCoMo i-mode pricing

Unofficial content providers (53 000)
- Content-based fee (possibly free)
  - 70% free content
  - Premium content: 0.39-2.34€/service/month

Official content providers (3000)
- 9% of content fee
  - 2.34€/month
  - Fixed fee
  - 0.0023€/packet (128B) = 18€/MB

End-user

1. Accounts for 87% of the i-mode ARPU
2. Accounts for less than 1% of the I-mode ARPU

Pricing of telecom equipment

• Traditionally pricing is based on hardware capacity (e.g. switching centers, routers, base stations), which hides software R&D costs → pressure to price software

• Capacity pricing is adapted per type of capacity
  – GSM MSC switching capacity (number of simultaneous calls)
  – GSM HLR storage capacity (number of subscribers)
  – GSM BTS capacity (number of TRXs)
  – IP router capacity (bits/sec, packets/sec, number of ports, etc)
  – Server transaction capacity (SMS/sec, locations/sec, etc)

• Growing exploitation of general purpose operating systems and hardware (e.g. Unix) in network elements is likely to un-bundle the pricing of software and hardware
