**Telecommunications Switching Technology** 

#### Some repetition

- ✓ Channel Associated Signaling (CAS) is tightly tied to the voice channel either in space, time or frequency -> no signaling unless voice channel is reserved.
- ✓ CAS has many limitations: in a PCM -frame one tsl needs to be dedicated to signaling and a multi-frame of 16 frames needs to be maintained. A set of signals is limited.
- ✓ Channel Associated R2-signaling is the first widely adopted, standardized CAS signaling system (but still not used in every country).
- **✓** R2 signaling is compelled.
- ✓ Call setup or register signaling vs. line signaling.

© Rka/ML -k2002

**Telecommunications Switching Technology** 

10 - 3

# ISDN -access has a set of standardized interfaces

- ✓ ISDN-access provides a bus for connecting user terminals, the max of 8 terminals can be attached.
- $oldsymbol{
  u}$  Many interfaces are specified between logical entities in the

Page 2

Two independent terminals can use one B-channer each at a time

The main purpose of the D-channel is transport of signaling between the terminals and the local ISDN exchange. Packet mode transfer is used on the D-channel.

© Rka/ML -k2002

**Telecommunications Switching Technology** 

10 - 5

## Message based signaling systems

- ✓ Message based signaling has been developed to improve the control possibilities of the network by terminals.
- ✓ Message based signaling can be used only by Computer controlled, fully digital exchanges.
- ✓ Message based signaling is natural for computers the signaling information is largely in the same format in which it is processed and stored.
- ✓ Message based signaling is based on ITU-T:n SS6 (now CCS7 and ISDN) recommendations.

## (U ja V) -interfaces

#### ✓ Network Termination NT1 is connected to the exchange Line Termination using the U-interface.

- Data transfer takes place on a twisted pair copper cable (BRI), the bit rate is 160 kbit/s bi-directionally (full duplex).
- > In Finland (originally in US) multi level code 2B1Q is used ( -> baud rate is 80 kbaud).
- > Bi-directional full duplex transfer is based on echo cancellation.

#### ✓ On the V-interface a number of specifications may be used.

- > V1-interface applies for the Basic rate interface.
- > V3-interface is meant for PBXs with a capacity of 30B+D<sub>64</sub> channels.

© Rka/ML -k2002

**Telecommunications Switching Technology** 

10 - 11

## (S, T) -Interfaces

#### ✓ S-interface is meant for terminals.

- > The interface is a bus by structure
- > 8 ISDN terminals can be connected.
- > Transfer in both directions uses 4 wires.

#### ✓ T-interface is meant for PBXs

- Resides between network termination NT1 and an ISDN-PBX (= NT2).
- T0-interface = S0-interface and is used in PBXs that can serve only BRI connected users.

#### ✓ T2-interface is meant for corporate PBXs

- > Transfer rate is 2048 kbit/s.
- T2-interface has 32 channels with 64 kbit/s. Of those 30 are normal B-channels, one is the D-channel and one is used for synchronization. I.e. the structure is like a PCM.

© Rka/ML -k2002

**Telecommunications Switching Technology** 

#### R -interface

✓ R-interface separates the Terminal Adapter and a non-ISDN device from each other. It follows some existing specification understood by the non-ISDN device (e.g. V.24, V.35 or X.21 - protocol specification).

© Rka/ML -k2002

**Telecommunications Switching Technology** 

10 - 13

# In practice logical functions are grouped in the equipment

U-interface (twisted pair)

A Home-ISDN "NT" is likely to look like this. DIP switches are used for configuration.

Here physical "NT" = NT1+TA(for analogue phones)

© Rka/ML -k2002

**Telecommunications Switching Technology** 

#### Communication between NT and a Terminal

✓ AMI -line code is used between a Terminal and the NT (AMI, Alternate Mark Inversion).

✓ When there is not traffic over an ISDN interface, terminals are deactivated. A continuous INFO 0 signal is on the the interface.

© Rka/ML -k2002

**Telecommunications Switching Technology** 

10 - 15

# Activation of the basic rate interface

- ✓ Terminal starts activation by sending a continuous activation request: INFO 1. When the network detects the request, it starts sending synchronization frames INFO 2.
- ✓ When the network initiates activation, it starts sending INFO 2 directly.
- ✓ When the terminal detects a synchronization frame, it stops sending the activation request signal and starts sending active state frames INFO 3. When the local exchange has received active state frames, it moves to INFO 4 state. The physical layer is now active and ready for information transfer.

© Rka/ML -k2002

**Telecommunications Switching Technology** 

## Frame structure on the S-interface

- √ 48 bit frames 4000 times per second are used between a terminal and the NT1.
- ✓ The resulting bit rate is 192kbit/s

# Frame synchronization

- ✓ Frame synchronization is achieved by sending violation bits in the AMI code.
- ✓ The first (F) and the 14th bit (FA) equal to zero with a
  wrong polarity I.e. the same as the previous zero. To
  balance this for the sake of zero average voltage, the
  wrong zero is followed by DC balance bit (L).

NB: On S-interface the AMI code is inverted, I.e. logical zero is sent as a pulse with alternating polarity and a logical 1 is sent as zero voltage.

© Rka/ML -k2002

**Telecommunications Switching Technology** 

# Overhead bit in the frame carry D-ch echo and control power consumption

- ✓ A Terminal can see that the NT has received its Dchannel bits based on E(echo)-bits. NT copies a received D-bit to the next E-bit.
- ✓ A-bit is used for power control. With A-bit, the network
  can command the terminals to deactivate themselves and
  to transfer to a low power mode in which they are only
  able to become active again either on network request or
  user action. The activation procedure uses the A bit.

10 - 19

10 - 20

# Message based signaling can be functionally split following the OSI 7 layer model Application layer Presentation layer Session layer Transport layer Network layer Link layer Physical layer Physical layer

**Telecommunications Switching Technology** 

# Bearer services are transport services that are seen by the "user"

- ✓ Circuit switched bearer services include:
  - > Speech
  - > 3,1 kHz audio
  - > 7 kHz audio
  - > transparent 64 kbit/s.
- **✓** Packet switched bearer services include:
  - > virtual call and permanent virtual connection,
  - > connectionless packet switched service on the D-channel,
  - > user-to-user signaling information.

© Rka/ML -k2002

**Telecommunications Switching Technology** 

10 - 21

# Telecommunication Services incorporate all OSI layers

- ✓ A Telecommunication service is a set of functions offered to a user and it is implemented using the capabilities of all OSI layers.
- ✓ Telecommunication services make use of the bearer services.
- ✓ Telecommunication services can by further divided into basic and supplementary services.
- ✓ Supplementary services can be used only in connection with a basic service.

© Rka/ML -k2002

**Telecommunications Switching Technology** 

#### Digital Signaling System Nr 1 (DSS 1)

- ✓ DSS1 is based on a protocol stack that includes three OSI lower layers.
- ✓ DSS1 is fully message based and out-of-band offering the possibility of signaling while the voice channel is open end-to-end.
- **✓** DSS1 messages are sent on the D-channel.
- ✓ DSS1 layer 2 follows the HDLC principles and is called the LAPD-protocol (Q.920 - Q.921).
- ✓ DSS1 signaling overview is given in ITU-T Q.930 and detailed procedures are given in Q.931.

© Rka/ML -k2002

**Telecommunications Switching Technology** 

10 - 23

### Q.920/Q.921 - LAPD

- ✓ Connectivity over the link between a terminal and the Local exchange
  - > Inherits HDLC principles.
  - > Corresponds to the OSI layer 2 requirements
- ✓ Transfers frames from many terminals to many layer 3 entities.
- ✓ Properties:
  - DLCI data link connection id identifies the link connections: DLCI = SAPI + TEI. SAPI = Service Access Point Id, TEI = Terminal Endpoint Id are purely layer 2 concepts. Layer 3 uses CEI Connection Endpoint Id = (SAPI+CES)
  - > Can guarantee frame order due to numbering.
  - > Fault management lighter than MTP in CCS#7.
  - > Flow control based on windowing.

© Rka/ML -k2002

**Telecommunications Switching Technology** 

## Q.921 - LAPD

- ✓ Point-to-point link connections, multi-point connections broadcast
- ✓ Initiation state TEI values not yet chosen.
- ✓ Unnumbered Information = UI -frames are not acknowledged
  - > also broadcast (e.g. SETUP to B subscriber)
  - > faults recovery is left for the upper layers.
- ✓ Acknowledged mode I numbered frames
  - $\qquad \hbox{ fault recovery and flow control procedures supported on layer 2} \\$

© Rka/ML -k2002

**Telecommunications Switching Technology** 

### DSS1 - Q.931 - signaling

- ✓ Corresponds to layer 3 network layer:
  - > understands end-to-end addresses: E.164 telephone numbers
- ✓ Can set up, control and release circuit switched calls.
- ✓ Supports also packet switched on-demand connections.
- ✓ Call identification is based on the call reference and has nothing to do with e.g. the identity of the B-channel in use!
- ✓ Supports the functional and the stimulus (keypad) modes of signaling.
- ✓ User-to-user information transfer in signaling messages is also supported (charging is an issue).

© Rka/ML -k2002

**Telecommunications Switching Technology** 

10 - 27

#### Functional and stimulus -modes

#### **✓** Functional

- Information is encoded in service specific information elements.
- As a result, signaling becomes service dependent. A new service requires new programs both in the CPE and the exchange
- > Can be OK, if CPE = PBX
- > For phones would really require a JAVA -like automatic software download function. There is no such thing in ISDN!

#### ✓ Stimulus -mode:

- phone button pushes are carried in signaling as such,
- > Interpretation is the responsibility of the exchange
- > A new service requires new programs only in the network
- The phone may have programmable soft keys to hide dialing sequences

© Rka/ML -k2002

**Telecommunications Switching Technology** 

# **ISDN Summary**

- ✓ Signaling and voice channel are both physically and logically separated (out-of-band, common channel + call reference).
- ✓ Any signaling info needed for services is supported or can be added.
- ✓ Q.931 signaling is service dependent, contains really information that is relevant on OSI-layers 3 - 7! New services require new programs in CPEs in case of functional mode. There is no mechanism for automatic software download to CPEs.
- **✓** Multi-point structure complicated the implementation significantly.
- ✓ Major consumer value added is in 2 x 64kbit/s bit rate. ISDN adoption is determined by home Internet use.
- ✓ ISDN specified a digital PBX access signaling for the first time. This has been widely adopted! ISDN signaling has been reused in many new signaling applications (V5, private PBX networks, IP-Telephony, conferencing, GSM etc.)
