NAME
Berl_i, Berl_d, Xerl, Aerl - Erlang and inverse Erlang functions

## SYNOPSIS

\#include <erlang.h>
double Berl_i(int n, double a);
double Berl_d(double $x$, double a);
double Xerl(double b, double a);
double Aerl(double $x$, double b);
DESCRIPTION
These functions give solutions to the Erlang blocking formula. Erlang formula gives the probability that a communications system with $n$ (or $x$ ) lines can't handle any more calls. This also depends on the traffic intensity $a$. All arguments to these functions must be positive and $0<b<1$.

Berl_i() returns the Erlang loss probability for a integer valued trunk group $n$ and Poisson traffic $a$
Berl_d() returns the Erlang loss probability for a trunk group $x$, where $x$ is a real valued variable (double). Second parameter is the Poisson traffic $a$.
Xerl() returns the number of trunks for a loss probability $b$ and Poisson traffic $a$.
Aerl() returns the Poisson traffic value for a trunk group $x$ and loss probability $b$.

## ALGORITHM

Berl_i() is implemented by using the recursion formula
(1) $\$ \mathrm{E}(\mathrm{x}+1, \mathrm{a})=\{\mathrm{a} \mathrm{E}(\mathrm{x}, \mathrm{a})\}$ over $\{\mathrm{x}+1+\mathrm{a} \mathrm{E}(\mathrm{x}, \mathrm{a})\} . \$$

Berl_d() is divided into five sections depending on the value of the parameters.
Range 1: $\mathrm{x}<\mathrm{a}$ and $\mathrm{a}>0.01$
Apply the continued fraction expansion formula.
Range 2: $x>=a$ and $x>60$
Determine a value $x$ ' such that $a>x$ x (i.e. apply an integral valued shift of $x$ ). Call Berl_d again with $x$ ' < a and use the recurrence relation to arrive at the original value of $x$.

Range 3: $x>=a$ and $1<=x<=60$
Apply Rapp's parabola followed by the recurrence relation (1).
Range 4: $\mathrm{x}>=\mathrm{a}$ and $\mathrm{a}>0.01$ and $\mathrm{x}<1$
Apply Laguerre quadrature, Abramowitz [2], p. 923
Range 5: $0<\mathrm{x}<1$ and $0<\mathrm{a}<=0.01$
Apply formula (48) from Farmer and Kaufman [ref 1], p. 161
In Xerl() we first determine with inequality
$\mathbf{E}(\mathbf{n}, \mathbf{a})>E(\mathbf{n}+\mathbf{1}, \mathbf{a})$
the position of the interval $[\mathrm{N}, \mathrm{N}+1]$ such that $\mathrm{N} \ll \mathrm{X}<=\mathrm{N}+1$. By using the secant iteration method, we determine the exact root of the function

$$
\mathbf{f}(\mathbf{x})=\text { Berl_d }(\mathbf{x}, \mathbf{a})-\mathbf{b} .
$$

Evaluation time of $\overline{\mathbf{X}} \mathbf{e r l}()$ is proportional to the result value.
Aerl(): First we compute a starting value for $a$. Then $a$ is improved using the Newton's iteration scheme. The iteration process is stopped as soon as the relative error in $\mathrm{E}(\mathrm{x}, \mathrm{a})$ is smaller than some prescribed value. When $b$ is very small, this function has long evaluation time.
