# Measurements of Quality Differentiation

Jari Huttunen

Helsinki University of Technology

Networking laboratory

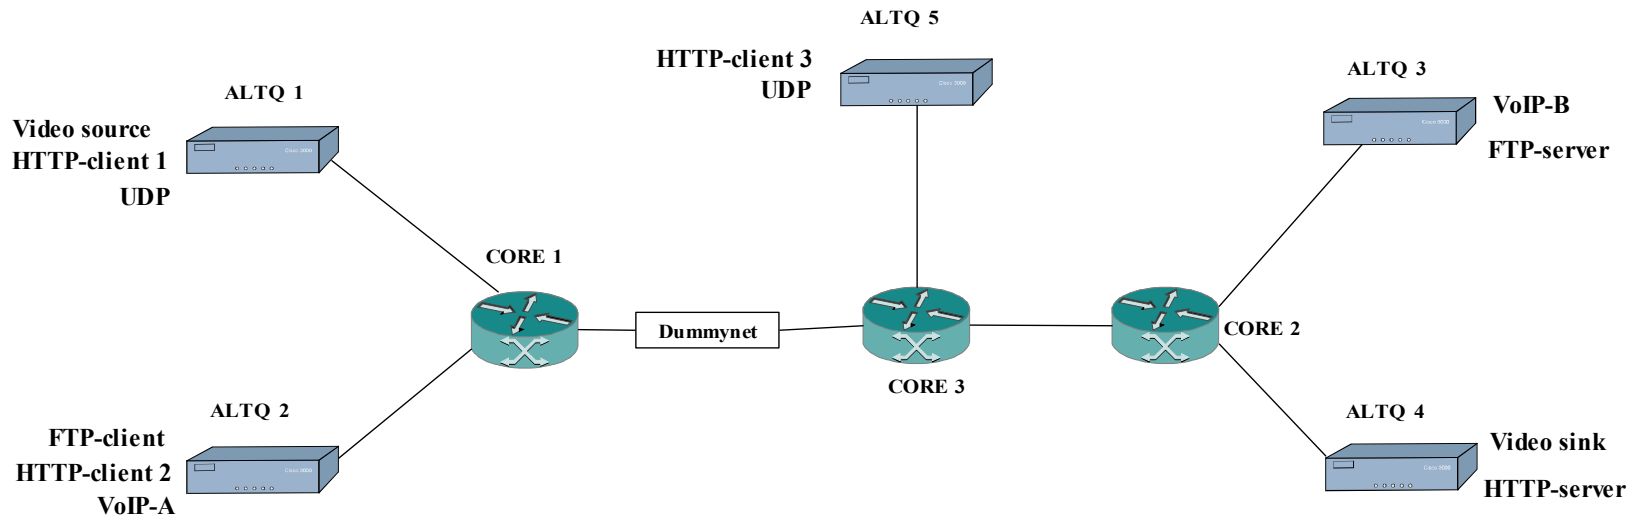

# Contents

- Network prototype
  - Topology and system configuration
- Traffic generation
  - Traffic generators and traffic tracing
- Applications
- Theory
  - PHBs
    - Assured Forwarding
    - Expedited Forwarding
- Test cases
  - Best Effort (BE)
  - Expedited Forwarding (EF)
  - Assured Forwarding (AF)
  - EF + AF
  - AF: Bad provisioning
- Summary
- Conclusions
- Future work

# Network prototype

- Standard PC-hardware
  - AMD 1300 MHz/256 MB
  - 4 \* 3Com 10/100 Ethernet NICs
- 3 core and 5 edge routers
- Dummynet network emulator
  - 30 ms extra delay (low and high delay paths)
- Several traffic generators

# System configuration

- FreeBSD OS with ALTQ-package
  - QoS mechanisms (queueing, scheduling, shaping, metering, marking)
- All NICs configured to 10Base-Tx full duplex
- CBQ is used in traffic shaping
  - WRR as a general scheduler
- Static provisioning, no borrowing between classes
  - Capacity differentiation (a predefined amount of link capacity for each traffic class)
- Queue management: tail-drop, RED, RIO
- Token Bucket (TB) and two rate Three Color Marker (TrTCM) used for metering/marking (color blind)

# Traffic generation

- Applications with different properties
  - Real time / non-real time
  - Bandwidth sensitive / delay sensitive
  - TCP / UDP based
  - Constant bitrate / varying bitrate
  - Long “friendly” TCP flows / short “aggressive” flows
- How to carry all this traffic in a single network and same time provide quality of service?

# Traffic generation (cont.)

- Traffic generators
  - SmartBits 600
  - PC hardware
- SmartBits 600
  - SmartMetrics 10/100 BaseT Ethernet module
  - SmartVoIPQoS
    - A test application to stress and analyze the networks ability to carry voice and data traffic simultaneously
    - Can generate multiple IP flows and simulate VoIP gateways and phones
    - Measure delay, jitter, throughput and packet loss (+define overall voice quality)

- PC hardware
  - Linux / FreeBSD TCP stack implementation
  - Synchronized by using Network Time Protocol (NTP)

# Traffic tracing

- SmartBits 600 can trace the traffic it sends and give aggregated results
  - Transmit flows → Collect data from cards → Display results
- We perform also packet capturing using Tcpdump at client and server side
  - Analysis of TCP traffic
    - RTT, throughput etc.
  - Packet captures are analyzed with Tcptrace tool (<http://irg.cs.ohiou.edu/software/tcptrace/index.html>)

# Applications

- VoIP
  - SmartBits 600 and SmartVoIPQoS software
  - G.711  $\mu$ -law voice coding with 20 ms framing
    - Packets size of 218 Bytes
  - We apply 20 flows per client, bi-directional
    - =40 VoIP flows
  - Silence detection is not being modelled
    - Constant bitrate application
  - Mapping to PSQM (Perceptual Speech Quality Measure) voice scoring system (0.4→6.5)
    - Comparing measurement results to a matrix that includes mappings between PSQM scores and the effect of impairments (jitter, packet loss)
    - Low PSQM value indicates of high voice quality
    - PSQM values are affected by:
      - Frame loss
      - Jitter
      - Type of codec used

# Applications (cont.)

- Video streaming
  - Rude/Crude UDP traffic generator/receiver
    - Used with video trace files
  - MPEG-4 encoded video stream from a movie
  - 25 frames per second (40 ms interval)
  - Mean bitrate 1.029 Mbps, max 8.797 Mbps
    - Varying bitrate application

Video stream data rate profile

# Applications (cont.)

- FTP
  - Client-server transactions
  - A modified version of Markus Peuhkuri's Klient-Server application
  - Packets size of 1500 B (MTU)
  - 50 individual file transfers
  - File size modelled by geometric distribution (mean 500 kB)
  - Example of long lasting TCP connections

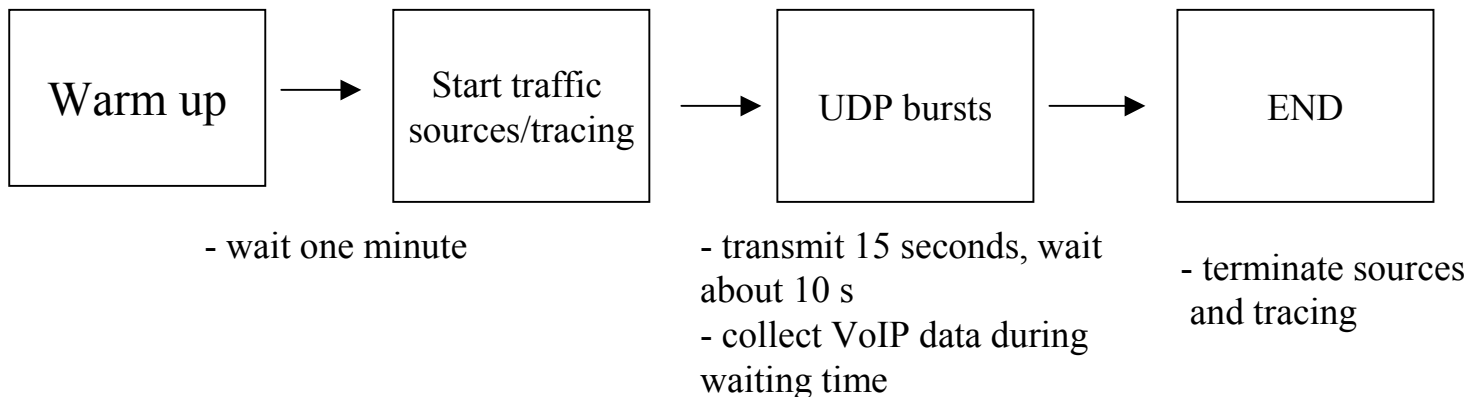

# Applications (cont.)

- HTTP
  - Apache 2.0 www-server
    - Most popular web server in the Internet
  - Siege is used at the client side
    - http testing and benchmarking utility
    - Simulates a predefined number of users
    - Reports of response times, amount of data transferred, etc.
  - 2 clients with high delay paths and 1 client (client #3) with a low delay path
    - Study the effect of dissimilar RTT
  - HTTP 1.0
  - Simulating 165 users
  - Object size modelled by geometric distribution (mean 10 kB)
  - Reading time 12 s
  - Example of short, interactive TCP connections

# Test procedure

- A one minute warm up period before actual measurements
  - To ensure that network is in stable condition
- We apply 15 seconds UDP bursts to congest the network
  - Packets of size 512 B (8 Mbit/s)
    - Does not aim to model any particular application
    - An aggressive, unresponsive source
  - VoIP flows
- We record all TCP traffic in the network for later analysis

# Per Hop Behavior (PHB)

- Defines the treatment how traffic belonging to a certain behavior group is forwarded at the individual network node
- DiffServ codepoint of a packet (DSCP) is used to select the PHB
- Two standardized PHB groups
  - Assured Forwarding
  - Expedited Forwarding

# Assured Forwarding (AF)

- Four independent forwarding classes with three drop precedences per class (RFC 2597)
- The forwarding assurance of an IP packet in a network node is determined by:
  - Resources allocated to the particular AF class
  - The current load of the AF class
  - Drop precedence of a packet

# Expedited Forwarding (EF)

- ”Leased line emulation”
  - Low loss, low latency and assured bandwidth service
- Defined in RFC 2598
- Strict queueing treatment
- Arrival rate  $<$  minimum service rate
  - Requires powerful forwarding from the router

# Test cases

- Case 1: Best Effort (BE): No differentiation between traffic flows
- Case 2: Expedited Forwarding (EF): EF service for VoIP flows.
- Case 3: Assured Forwarding (AF): Four independent forwarding classes.
- Case 4: EF+AF
- Case 5: AF: Different provisioning

# Connection pairs

- HTTP
- FTP
- VoIP

# Case 1: BE

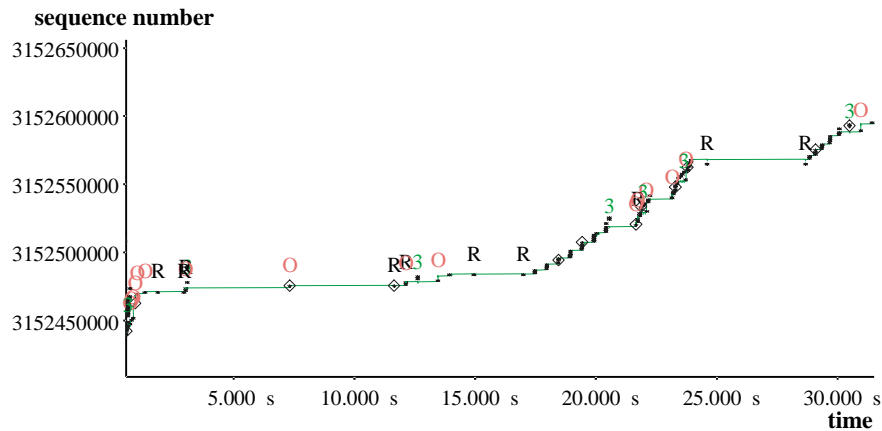

- Baseline (reference) for our studies
- No differentiation
  - Traffic sources are competing of the resources
  - Situation in today's Internet

# Case 1: BE (cont.)

- TCP is not able to send new data during congestion
- High delay and packet loss

TCP sequence number congestion (FTP connection)

Video streaming delay

|           | Packet loss (%) | PSQM | Avg latency (ms) | Avg jitter (ms) |
|-----------|-----------------|------|------------------|-----------------|
| A->B      | 14.57           | 3.16 | 220.87           | 1.95            |
| B->A      | 18.15           | 3.49 | 231.16           | 2.82            |
| Total avg | 16.36           | 3.3  | 225.56           | 2.37            |

VoIP

# Case 1: BE (cont.)

- Delays not acceptable, heavy packet loss
- http client (client 3) with low delay path is dominating

## HTTP

## FTP throughput

## HTTP

| Source   | Data transferred (B) | Response time (s) | Throughput (kbps) |
|----------|----------------------|-------------------|-------------------|
| Client 1 | 2751418              | 3.23              | 365.33            |
| Client 2 | 2616671              | 2.84              | 350.17            |
| Client 3 | 4272803              | 0.11              | 570.75            |

## Case 2: EF

- Two scenarios
  - 20 % of the link capacity provisioned for VoIP traffic
  - 30 % of the link capacity provisioned for VoIP traffic
- Other traffic sources get BE service
- Max delay set to 20 ms
- Leased line emulation

# Case 2: EF (cont.)

20 % provisioning

|           | Packet loss (%) | PSQM | Avg latency (ms) | Avg jitter (ms) |
|-----------|-----------------|------|------------------|-----------------|
| A->B      | 0.080           | 0.46 | 109.60           | 1.019           |
| B->A      | 0.067           | 0.45 | 98.56            | 1.271           |
| Total avg | 0.073           | 0.46 | 103.94           | 1.144           |

VoIP

30 % provisioning

|           | Packet loss (%) | PSQM | Avg latency (ms) | Avg jitter (ms) |
|-----------|-----------------|------|------------------|-----------------|
| A->B      | 0               | 0.4  | 30.870           | 1.123           |
| B->A      | 0               | 0.4  | 33.992           | 1.572           |
| Total avg | 0               | 0.4  | 32.431           | 1.348           |

- Increasing provisioning improves the quality of VoIP calls

–However, there is some oscillation in jitter

## Case 2: EF (cont.)

- Low delay path more dominant when more resources allocated for BE traffic
- EF can be used to provide a leased line emulation

80 % for BE service

| Source   | Data transferred (B) | Response time (s) | Throughput (kbps) |
|----------|----------------------|-------------------|-------------------|
| Client 1 | 2848275              | 2.68              | 380.66            |
| Client 2 | 3149460              | 2.35              | 421.12            |
| Client 3 | 4256773              | 0.14              | 565,5             |

HTTP

70 % for BE service

| Source   | Data transferred (B) | Response time (s) | Throughput (kbps) |
|----------|----------------------|-------------------|-------------------|
| Client 1 | 2814368              | 2.89              | 374.56            |
| Client 2 | 3352512              | 1.85              | 445.37            |
| Client 3 | 4088847              | 0.46              | 543.01            |

# Case 3: AF

| Class | Application | Bandwidth % | Buffer size | Conditioner | CIR (Mbps) | Peak rate (Mbps) |
|-------|-------------|-------------|-------------|-------------|------------|------------------|
| AF1   | VoIP+Video  | 50          | 20 ms       | TB          | 5          | N/A              |
| AF2   | HTTP        | 20          | 60 ms       | trTCM       | 4          | 5                |
| AF3   | FTP         | 18          | 120 ms      | trTCM       | 2          | 3                |
| AF4   | Other       | 10          | 360 ms      | trTCM       | 2          | 3                |

- Class AF1 for real time applications
  - Class AF2 for interactive TCP traffic (HTTP)
  - Class AF3 for non-interactive TCP traffic (FTP)
  - Class AF4 for the traffic that does not conform to AF1, AF2 or AF3
- 2 % of resources is assigned for the control traffic

# Case 3: AF (cont.)

## FTP throughput

- FTP throughput is bounded to about 1.8 Mbit/s (the target rate for class AF3)

# Case 3: AF (cont.)

- Fairness between HTTP clients
  - AF helps to diminish the effect of RTT
- Real time applications get decent quality of service
- TCP sources achieve (almost) their target rate

Video streaming delay

VoIP

|           | Packet loss (%) | PSQM | Avg latency (ms) | Avg jitter (ms) |
|-----------|-----------------|------|------------------|-----------------|
| A->B      | 1.06            | 1.02 | 32.27            | 2.28            |
| B->A      | 0.0             | 0.4  | 34.77            | 3.91            |
| Total avg | 0.53            | 0.7  | 33.48            | 3.10            |

HTTP

| Source   | Data transferred (B) | Response time (s) | Throughput (kbps) |
|----------|----------------------|-------------------|-------------------|
| Client 1 | 3742733              | 1.26              | 500.20            |
| Client 2 | 3744647              | 1.27              | 501.21            |
| Client 3 | 3931651              | 0.79              | 522.31            |

# Case 4: EF+AF

| Class | Application | Bandwidth % | Buffer size |
|-------|-------------|-------------|-------------|
| EF    | VoIP        | 20          | 20 ms       |
| AF1   | Video       | 30          | 20 ms       |
| AF2   | HTTP        | 20          | 60 ms       |
| AF3   | FTP         | 18          | 120 ms      |
| AF4   | Other       | 10          | 360 ms      |

- A finer differentiation between real time applications
  - EF PHB for VoIP flows
- Otherwise same as in previous case

# Case 4: EF+AF (cont.)

## HTTP

| Source   | Data transferred (B) | Response time (s) | Throughput (kbps) |
|----------|----------------------|-------------------|-------------------|
| Client 1 | 3613647              | 1.45              | 483.75            |
| Client 2 | 3760971              | 1.29              | 495.84            |
| Client 3 | 3922848              | 0.82              | 525.32            |

- VoIP and HTTP flows experience similar QoS as in AF case

## VoIP

|           | Packet loss (%) | PSQM | Avg latency (ms) | Avg jitter (ms) |
|-----------|-----------------|------|------------------|-----------------|
| A->B      | 0               | 0.4  | 32.199           | 1.807           |
| B->A      | 0.040           | 0.43 | 34.386           | 3.665           |
| Total avg | 0               | 0.4  | 33.293           | 2.736           |

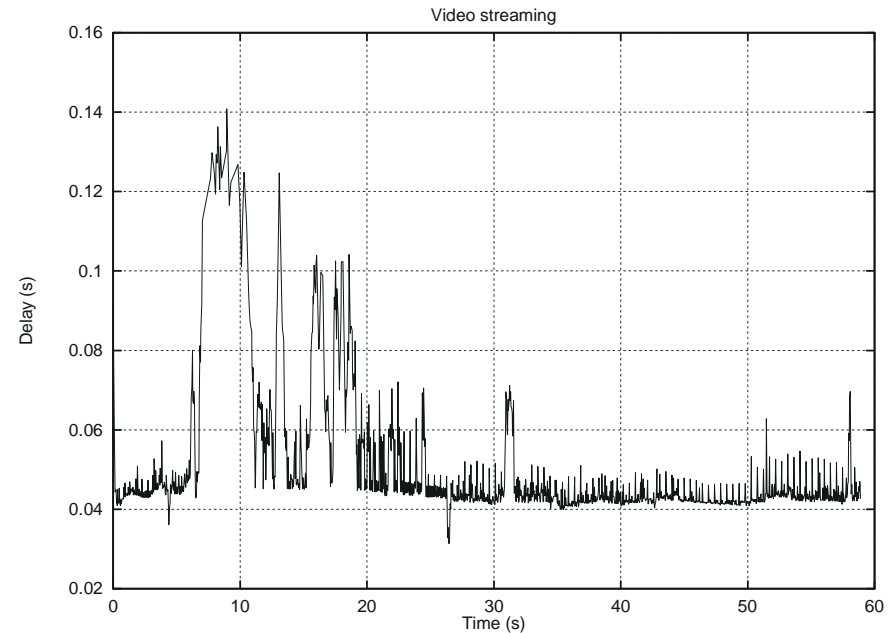

# Case 4: EF+AF (cont.)

- Resources are exhausted during the first UDP burst in AF1 class (video streaming)
  - Bad provisioning (overload in the class)

Video streaming delay variance / packet loss

Video streaming delay

# Case 5: AF different provisioning

| Class | Application | Bandwidth % | Buffer size | Conditioner | CIR (Mbps) | Peak rate (Mbps) |
|-------|-------------|-------------|-------------|-------------|------------|------------------|
| AF1   | VoIP+Video  | 30          | 20 ms       | TB          | 5          | N/A              |
| AF2   | HTTP        | 40          | 60 ms       | trTCM       | 4          | 5                |
| AF3   | FTP         | 10          | 120 ms      | trTCM       | 2          | 3                |
| AF4   | Other       | 18          | 360 ms      | trTCM       | 2          | 3                |

- More bandwidth allocated for TCP traffic

# Case 5: AF different provisioning (cont.)

|           | Packet loss (%) | PSQM | Avg latency (ms) | Avg jitter (ms) |
|-----------|-----------------|------|------------------|-----------------|
| A->B      | 14.62667        | 3.21 | 32.026           | 1.768           |
| B->A      | 0               | 0.4  | 33.666           | 2.656           |
| Total avg | 0               | 1.81 | 33.846           | 2.212           |

VoIP

| Source   | Data transferred (B) | Response time (s) | Throughput (kbps) |
|----------|----------------------|-------------------|-------------------|
| Client 1 | 4148934              | 0.40              | 554.67            |
| Client 2 | 4136732              | 0.45              | 549.64            |
| Client 3 | 4251938              | 0.21              | 565.70            |

HTTP

# Summary

|          | VoIP | HTTP response time (s) |          |          | Video streaming |
|----------|------|------------------------|----------|----------|-----------------|
| Case     | PSQM | Client 1               | Client 2 | Client 3 | Packet loss %   |
| BE       | 3.3  | 3.23                   | 2.84     | 0.11     | 15.1            |
| EF (30%) | 0.4  | 2.89                   | 1.85     | 0.46     | 56.3            |
| EF (20%) | 0.46 | 2.68                   | 2.35     | 0.14     | 23.2            |
| AF       | 0.7  | 1.26                   | 1.27     | 0.79     | 2.46            |
| EF+AF    | 0.4  | 1.45                   | 1.29     | 0.82     | 7.69            |
| Case 5   | 1.81 | 0.40                   | 0.45     | 0.21     | 32.2            |

# Conclusions

- In Best Effort network the traffic sources are interfering with each other
- EF can be used to provide premium service
- AF helps to reduce the effect of RTT for TCP connections
  - Better fairness
- CBQ is not a perfect solution
  - Need for adaptive schedulers?
- It's all about provisioning
  - The problem of provisioning the resources
  - Need for dynamic provisioning
- Tuning the parameters is not easy

# Future work

- Test different mechanisms
  - Borrowing, different schedulers, queuing algorithms etc.
- Measurements using dynamic provisioning
- Adding more flows / connections per class
- More realistic traffic distribution
  - More TCP connections
- Deeper analysis on data
- Measurements using Adtech AX4000
- Development of centralized management platform
  - Easier to manage the network and traffic generators
